**Illness**

# New AACE-ADA Consensus Statement on Inpatient Glycemic Control

## ICU Setting

- Insulin infusion preferred
- Starting threshold not higher than 180 mg/dl
- Maintain BG 140-180 mg/dl (greater benefit likely end of this range)
- Lower targets (not evidence-based) may be appropriate in selected patients if already being successfully achieved
- <110 NOT recommended (not safe)

## Non-ICU Setting

- Most patients:
  - pre-meal BG <140 mg/dL
  - random BG <180 mg/dL
- More stringent targets may be appropriate in stable patients
- Less stringent targets may be appropriate in patients with severe comorbidities
- Scheduled SQ insulin with basal-nutritional-correction preferred; avoid prolonged therapy RISS alone

✓ **HbA1c**

# **Rationale for Good Glycemic Control in the Hospital**

- 1. Reduced mortality, complications, lower costs, & length of stay.**
- 2. Evidence in ICU > evidence on general wards**
- 3. Improved patient satisfaction**
- 4. Emerging focus of QI organizations**
- 5. Opportunity for patient (& family) education**
- 6. Staff training on 'best practice'**
- 7. Model good behaviors for trainees**

# The ICU

## Critical Care Insulin Infusion Protocol (IIP) for Adults

The following IIP is intended for use in hyperglycemic adult patients in the ICU or being transferred to the ICU from the PACU or ED. **It should NOT be used in diabetic ketoacidosis (DKA) or hyperosmolar hyperglycemic state (HHS), as these patients may require higher initial insulin doses, IV dextrose at some point, and important adjunctive therapies for their fluid/acid-base/electrolyte/divalent status.** In any patient with BG >500 mg/dL, the initial orders should also be carefully reviewed with the MD, since a higher initial insulin dose and additional monitoring/therapy may be required. If the patient's response to the insulin infusion is at any time unusual or unexpected, or if any situation arises that is not adequately addressed by this protocol, the MD must be contacted for assessment and further orders.

### Getting Started

- 1.) PATIENT SELECTION: Begin IIP in any critically ill patient with more than 2 BGs  $\geq 180$  mg/dl who is not expected to rapidly normalize their glycemic status. Patients who are eating (see #9 below); transferring out of ICU imminently ( $< 24$  hrs); or pre-terminal or being considered for CMO status not appropriate candidates for this IIP. **In the CTICU only, IIP initiation threshold is a single BG  $\geq 160$  mg/dl.**
- 2.) **TARGET BLOOD GLUCOSE (BG) RANGE:** **120-160 mg/dL**
- 3.) **ORDERS:** MD order required for use in the ICU.
- 4.) **INSULIN INFUSION SOLUTION:** Obtain from pharmacy (1 unit Regular Human Insulin / 1 cc 0.9 % NaCl).
- 5.) **PRIMING:** Before connecting, flush 20 cc infusion through all tubing.
- 6.) **ADMINISTRATION:** Via infusion pump in 0.5 units/hr increments.
- 7.) **BOLUS & INITIAL INFUSION RATE:** Divide initial BG level by 100, then round to nearest 0.5 units for bolus AND initial infusion rate.  
 Examples: 1.) Initial BG = 325 mg/dL:  $325 \div 100 = 3.25$ , round  $\uparrow$  to 3.5: IV bolus 3.5 units + start infusion @ 3.5 units/hr.  
 2.) Initial BG = 274 mg/dL:  $274 \div 100 = 2.74$ , round  $\downarrow$  to 2.5: IV bolus 2.5 units + start infusion @ 2.5 units/hr.
- 8.) **CAUTION:** If enteral/parenteral (TPN, PPN, Tube feeds) nutrition abruptly stopped, **reduce infusion rate by 50%.**
- 9.) Patients requiring IV insulin are usually not eating. If eating, consider giving SQ Aspart PC to 'cover' the meal (1 unit/15 grams carbohydrates consumed (usual dose 3-6 units.) Dose may be adjusted proportionate to the percentage of the tray consumed (e.g.,  $\frac{1}{2}$  dose if  $\frac{1}{2}$  tray eaten).
- 10.) Patients with T1DM, insulin-requiring T2DM, and those requiring  $> 1$  unit/hr should be transitioned to scheduled SQ insulin (i.e. **NOT** just regular insulin sliding scale) prior to discharge from ICU. Please contact Pharmacy or refer to the Pharmacy Intranet for the Transition Guidelines.

### BG Monitoring

While on infusion, use glucose meter to check BG **hourly**. Once stable (3 consecutive values in target range), may reduce checks to **q 2 hr**. If stable for 12-24 hrs, may space checks to **q 4 hr**. *Resume hourly checks until stable again if:* any BG out of range; any change in insulin infusion rate; any significant change in clinical condition; initiation/discontinuation of steroids, pressors, TPN/PPN/tube feeds, dialysis, CVVH, or CAVH. In patients who are vasoconstricted/hypotensive, capillary BG (i.e., fingersticks) may be inaccurate; venous or arterial blood is preferred in this setting.

### Adjusting Infusion Rate

#### If BG $< 50$ mg/dL:

**HOLD INSULIN INFUSION** & administer 1 amp (25 g) D50 IV; recheck BG q 15 minutes until  $\geq 90$  mg/dl.

➔ Then, recheck BG q 1 hr; when  $\geq 140$  mg/dL, wait 30 min, then restart infusion at 50% of most recent rate (rounded down to nearest 0.5 unit/hr.)

#### If BG 50-74 mg/dL:

**HOLD INSULIN INFUSION** & administer 1/2 Amp (12.5 g) D50 IV; recheck BG q 15 minutes until  $\geq 90$  mg/dl.

➔ Then, recheck BG q 1 hr; when  $\geq 140$  mg/dL, wait 30 min, then restart infusion at 50% of most recent rate (rounded down to nearest 0.5 unit/hr.)

#### If BG 75-99 mg/dL:

**HOLD INSULIN INFUSION.** Recheck BG q 15 minutes until BG reaches or remains  $\geq 90$  mg/dl.

➔ Then, recheck BG q 1 hr; when  $\geq 140$  mg/dL, wait 30 min, then restart infusion at 75% of most recent rate (rounded down to nearest 0.5 unit/hr.)

If BG  $\geq$  100 mg/dL:

**STEP 1:** Determine the CURRENT BG LEVEL - identifies a COLUMN in the table:

BG 100-119 mg/dL	BG 120-159 mg/dL	BG 160-199 mg/dL	BG $\geq$ 200 mg/dL
------------------	------------------	------------------	---------------------

**STEP 2:** Determine the RATE OF CHANGE from the prior BG level - identifies a CELL in the table - Then move right for **INSTRUCTIONS:**  
 [Note: If the last BG was measured 2 or more hrs before the current BG, calculate the hourly rate of change. Example: If the BG at 2PM was 150 mg/dL and the BG at 4PM is 120 mg/dL, the total change over 2 hours is -30 mg/dL; however, the hourly change is  $-30 \text{ mg/dL} \div 2 \text{ hours} = -15 \text{ mg/dL/hr.}$ ]

BG 100-119 mg/dL	BG 120-159 mg/dL	BG 160-199 mg/dL	BG $\geq$ 200 mg/dL	INSTRUCTIONS*
		BG $\uparrow$ by $> 60 \text{ mg/dL/hr}$	BG $\uparrow$	$\uparrow$ INFUSION by "2 $\Delta$ "
	BG $\uparrow$ by $> 40 \text{ mg/dL/hr}$	BG $\uparrow$ by 1-60 mg/dL/hr OR BG UNCHANGED	BG UNCHANGED OR BG $\downarrow$ by 1-20 mg/dL/hr	$\uparrow$ INFUSION by " $\Delta$ "
BG $\uparrow$	BG $\uparrow$ by 1-40 mg/dL/hr, BG UNCHANGED, OR BG $\downarrow$ by 1-20 mg/dL/hr	BG $\downarrow$ by 1-40 mg/dL/hr	BG $\downarrow$ by 21-60 mg/dL/hr	NO INFUSION CHANGE
BG UNCHANGED OR BG $\downarrow$ by 1-20 mg/dL/hr	BG $\downarrow$ by 21-40 mg/dL/hr	BG $\downarrow$ by 41-60 mg/dL/hr	BG $\downarrow$ by 61-80 mg/dL/hr	$\downarrow$ INFUSION by " $\Delta$ "
BG $\downarrow$ by $> 20 \text{ mg/dL/hr}$ see below <sup>†</sup>	BG $\downarrow$ by $> 40 \text{ mg/dL/hr}$	BG $\downarrow$ by $> 60 \text{ mg/dL/hr}$	BG $\downarrow$ by $> 80 \text{ mg/dL/hr}$	HOLD x 30 min, then $\downarrow$ INFUSION by "2 $\Delta$ "

<sup>†</sup>HOLD INSULIN INFUSION;  
 $\sqrt{\text{BG}}$  in 15 min to be sure  
 $\geq 90 \text{ mg/dl}$ . Then recheck BG  
 q 1 hr; when  $\geq 140 \text{ mg/dl}$ ,  
 restart infusion @75% of most  
 recent rate, rounded down to  
 the nearest 0.5 unit/hr.

**STEP 3:** CHANGES IN INFUSION RATE\* (" $\Delta$ ")  
 are determined by the current rate:

Current Rate (Units/hr)	$\Delta$ = Rate Change (Units/hr)	$2\Delta$ = 2X Rate Change (Units/hr)
< 3.0	0.5	1
3.0 – 6.0	1	2
6.5 – 9.5	1.5	3
10.0 – 14.5	2	4
15 – 19.5	3*	6*
$\geq 20^*$	4*	8*

\* Depending on the clinical circumstances, infusion rates typically range between 2-12 units/hr. Doses  $>20$  units/hr are unusual, and, if required, the responsible MD should be notified to explore other potential contributing factors (including technical problems, such as dilution errors, etc.)

Target BG: 120-160

Begin IV insulin:

BG  $\div$  100 = \_\_\_\_  
 U/hr

**A L E R T !!!**

Except for hypoglycemia, NEVER terminate infusion unless transition orders to SQ insulin are in place! Any patient with type 1 diabetes, on insulin before admission, or requiring  $>1.0$  units/hr should be transitioned to basal-bolus-correction (BBC) SQ insulin. Overlap with infusion by 2-3 hrs. (See 'YNHH Transition Guideline from IV Insulin Infusion.')

# Comparison of Yale IIPs, 2004-2011

# Remember to Transition to SQ Insulin!

- Any T1DM
- T2DM >1 u/hr

## Plan:

- Use recent hourly rate when stable
- Convert to total daily dose (TDD)
- TDD x 0.8
- 50% basal
- 50% nutritional
- Overlap 2-3 hrs

### Transition Guideline from IV Insulin Infusion

The following patients should ALWAYS be transitioned to scheduled subcutaneous (SQ) insulin when the intravenous (IV) insulin infusion is stopped:

- Type 1 diabetes (e.g., ketosis-prone; youth diagnosis; lean; labile control)
- Type 2 diabetes on insulin prior to admission.
- Anyone requiring >1 unit/hour of insulin infusion

For all others, use Sliding Scale: Lispro pre-meal if eating; Regular Q6hrs if NPO (start with 'mid-dose' scale.)

The 'B-B-C' insulin protocol (see Epic, under Order Sets) is the preferred regimen in most patients (*see below*). If previously treated with insulin, resumption of the outpatient regimen can also be considered, depending on patient's status and the recent quality of blood glucose control as denoted by patient report and recent HbA1c.

**STEP 1** : Average amount of IV insulin/hr required over last 4 hrs =  units/hr  
(best calculated if IV rate stable and no meals consumed.)

**STEP 2** : Multiply this number by 24 hrs = approximate total daily insulin needs =  units/day

**STEP 3** : Take 80%\* of this number ('safety factor') =  units/day

**STEP 4** : Divide this amount into 50% Basal and 50% Bolus insulin:

50% =  units/day as **BASAL** insulin†

50% =  units/day as mealtime **BOLUS** insulin†

**NOTE !**  
Maximum initial basal dose coming off drip is: 0.5 units/kg/day

**STEP 5** : ÷ **BOLUS**† insulin into 3 equal parts & give TID AC =  units/meal  
(assuming roughly equal carbohydrate content at each meal.)

**NOTE !**  
Maximum initial mealtime bolus dose coming off drip is: 0.1 units/kg/meal

**STEP 6** : Add "CORRECTION" insulin‡ to adjust for pre-meal hyperglycemia to mealtime **BOLUS** dose  
(same type of insulin as the bolus!)

**ALWAYS OVERLAP INSULIN INFUSION BY AT LEAST 1 HOUR AFTER ANY SQ RAPID-ACTING INSULIN OR 2-3 HOURS AFTER ANY SQ LONG-ACTING INSULIN !!!**

\* In patients who are tenuous, hypoglycemia-prone, or who were receiving at least 75 cc/hr of D5 containing IV fluids while on the insulin infusion, consider using a lower % (e.g., 60-70%) as the 'safety factor' in **STEP 3**.

† Glargine (Lantus) is preferred basal insulin – may be injected at any time, Q24h. May use NPH, but dose BID, ideally QAM + QHS.

‡ Lispro (Humalog) is preferred mealtime bolus. This fixed mealtime dose will prevent post-prandial glucose spikes.

§ See Correction Insulin table for proper dosing, based on estimation of patient's insulin sensitivity.

#### SPECIAL CIRCUMSTANCES

1. **The Patients on Tube Feeds:** Give 50% of amount in **STEP 3** as Basal and the balance as Regular Q 6 hrs (plus Regular Correction Scale.) This will allow more rapid adjustment of insulin dose if tube feeds stop.

2. **The Patient on TPMPN:** Use protocol for Tube Feed Patients in #1 above. An alternative, in T2DM, is to provide the amount in **STEP 3** within IV nutrition solution, to be distributed over 24 hrs (+ SQ Regular Insulin Sliding Scale.) In T1DM, can add 50% of **STEP 3** amount within IV nutrition solution and the balance as SQ Basal insulin (+ SQ Regular Insulin Sliding Scale.) Confirm all calculations with Pharmacy.

An aerial photograph of a city, likely New York City, showing a dense urban landscape. In the foreground, a large, multi-story hospital complex with a tan facade and numerous windows is prominent. The hospital has several interconnected buildings and a central courtyard area. The surrounding city features a mix of residential and commercial buildings, including a tall, dark skyscraper in the background. The text "The Wards" is overlaid in a large, blue, serif font across the center of the image.

# Insulin Orders in the Hospital

What to do depends on several questions...

Who  
is  
the  
patient?

- Type 1?
- Type 2?

Which is  
the  
outpatient  
regimen?

- Orals?
- Insulin?
- Combo?

How well  
is it  
controlling  
glucose?

- A1c 6.5%?
- A1c 9.5%?

What is  
the current  
glucose?

- BG=142?
- BG=442?

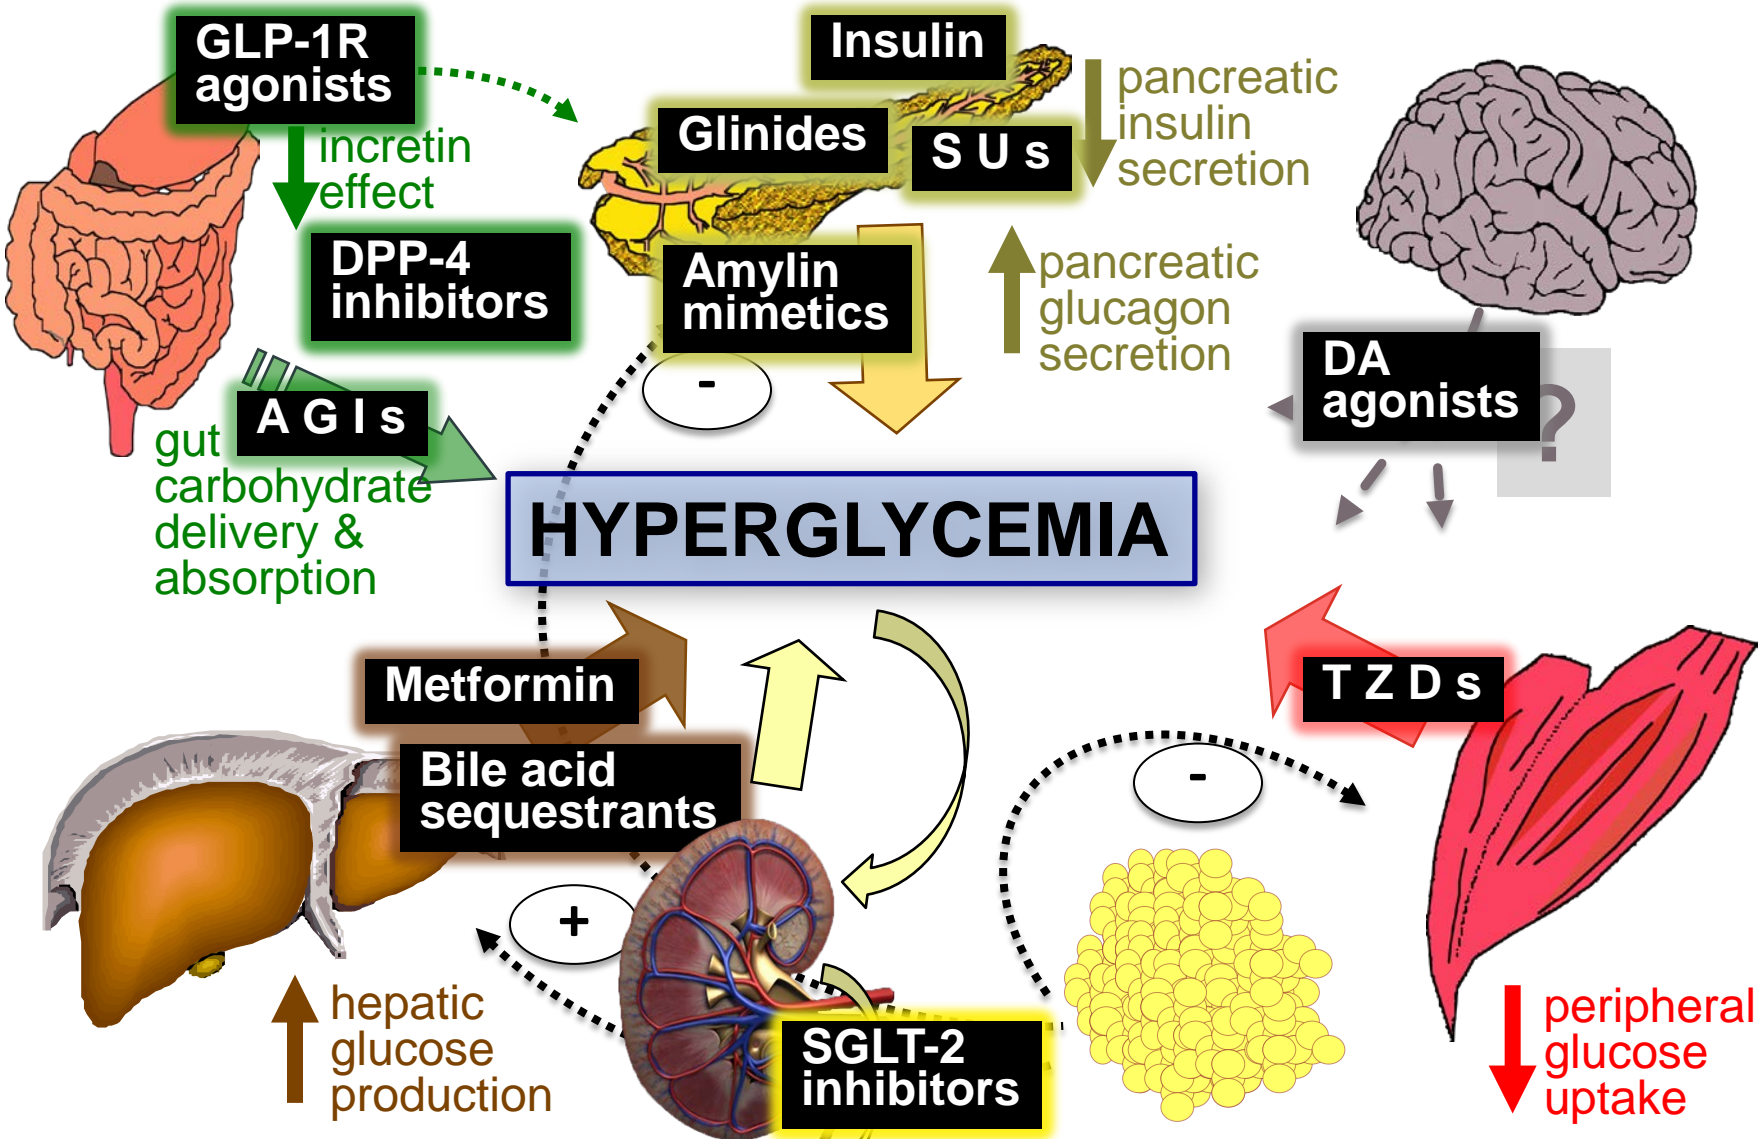

When is  
the patient  
to eat?

- NPO?
- Full diet?

Why is the  
patient  
admitted?

- Sepsis?
- A-Fib?

# Multiple Pathophysiologically-Based Therapies for T2DM

# Normal Secretory Pattern of Insulin

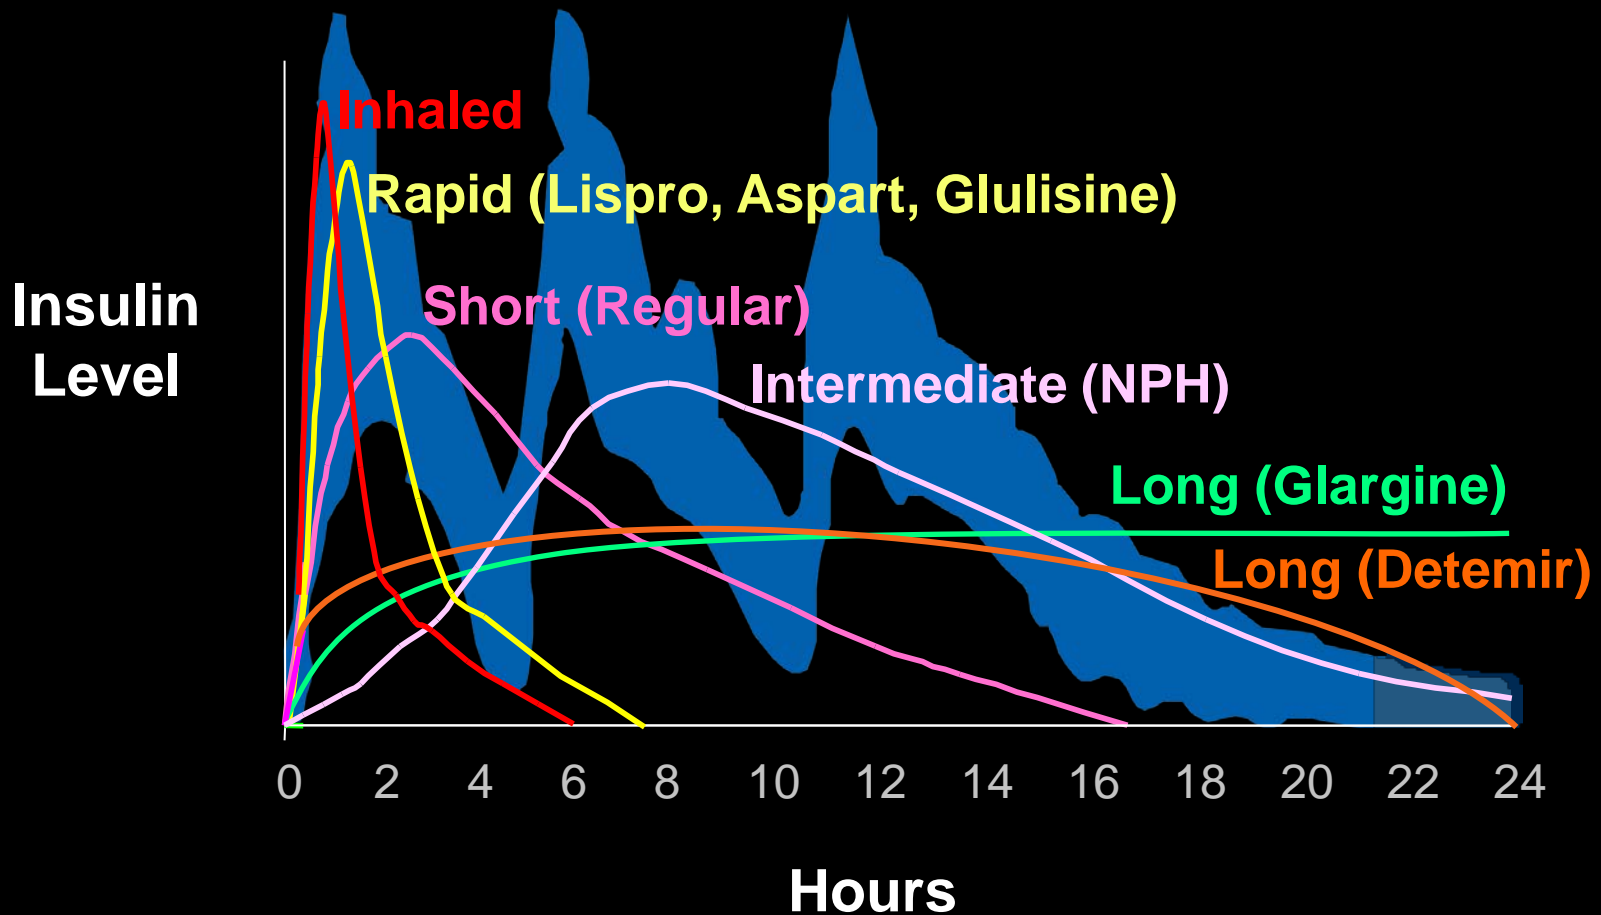

# Comparison of Human Insulins & Insulin Analogues

	<b>Insulin Type</b>	<b>Onset of Action</b>	<b>Peak Action</b>	<b>Duration of Action</b>
RAPID SHORT INTER BASAL	Lispro/Aspart*	5-15 min	1-2 hours	4-6 hours
	Human Regular	30-60 min	2-4 hours	6-10 hours
	Human NPH	1-2 hours	4-8 hours	10-18 hours
	Glargine	3 hours	flat	~24 hours
	Detemir	2 hours	somewhat flat	12-24 hours

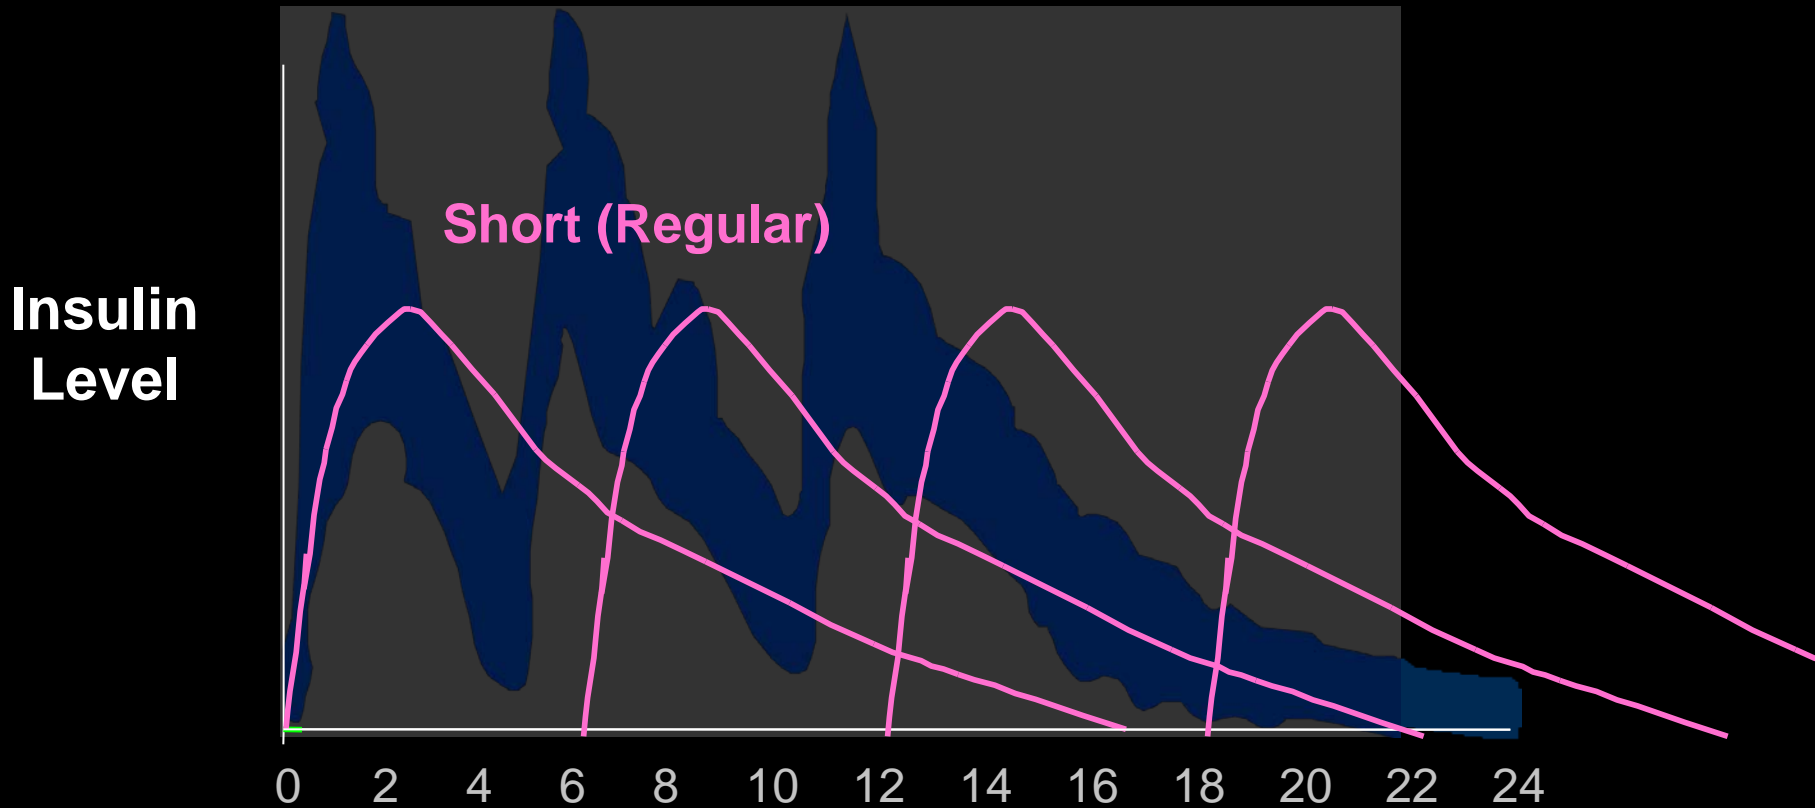

The time course of action of any insulin may vary in different individuals, or at different times or different injection locations in the same individual. Due to such variation, the time periods described above should be used as general guidelines only.

\* Glulisine is a 3<sup>rd</sup> rapid analogue

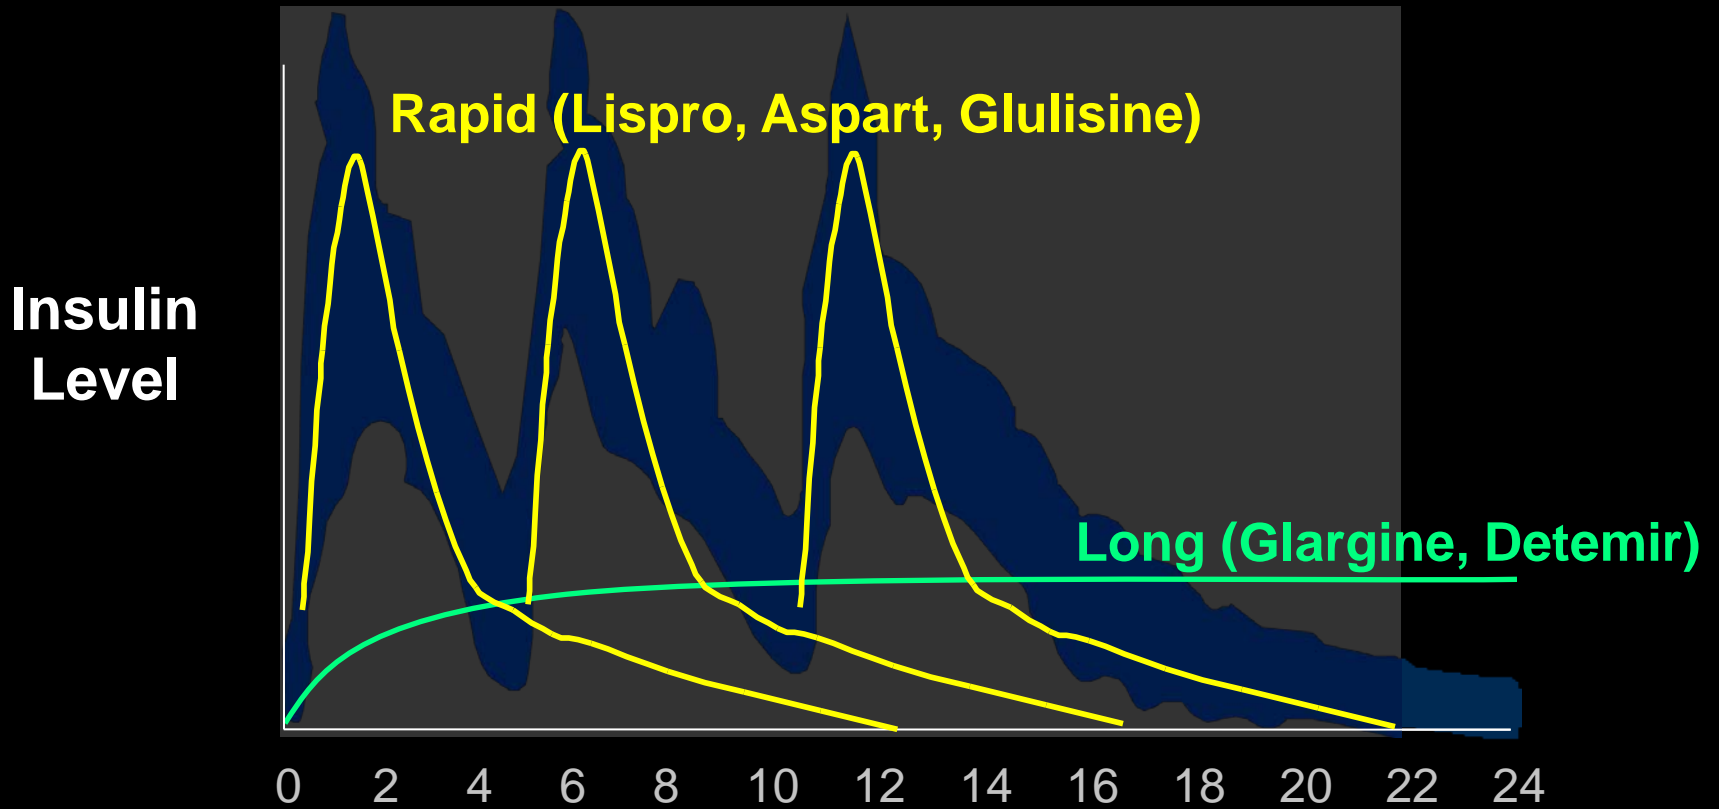

# Pharmacokinetics of Insulins

# Regular Insulin “Sliding Scale” (RISS)

# “Basal - Bolus” Insulin Therapy

# “Basal - Bolus” Insulin Therapy

# RABBIT-2 Study: Basal/Bolus vs. RISS in Non-ICU Patients

- Primary endpoint: differences in the mean daily BG
  - Mean overall BG difference between the groups during hospital stay was 27 mg/dL ( $P < 0.01$ )

N=130 insulin-naïve medical service pts, BG 140-400 mg/dl

# RABBIT-Surgery Trial: Study Design

238 Patients with type 2 DM that underwent general surgery

OPEN-LABELLED RANDOMIZATION

Glargine + Glulisine  
(Gla+Glu)  
N= 104

Sliding scale insulin  
(SSI)  
N= 107

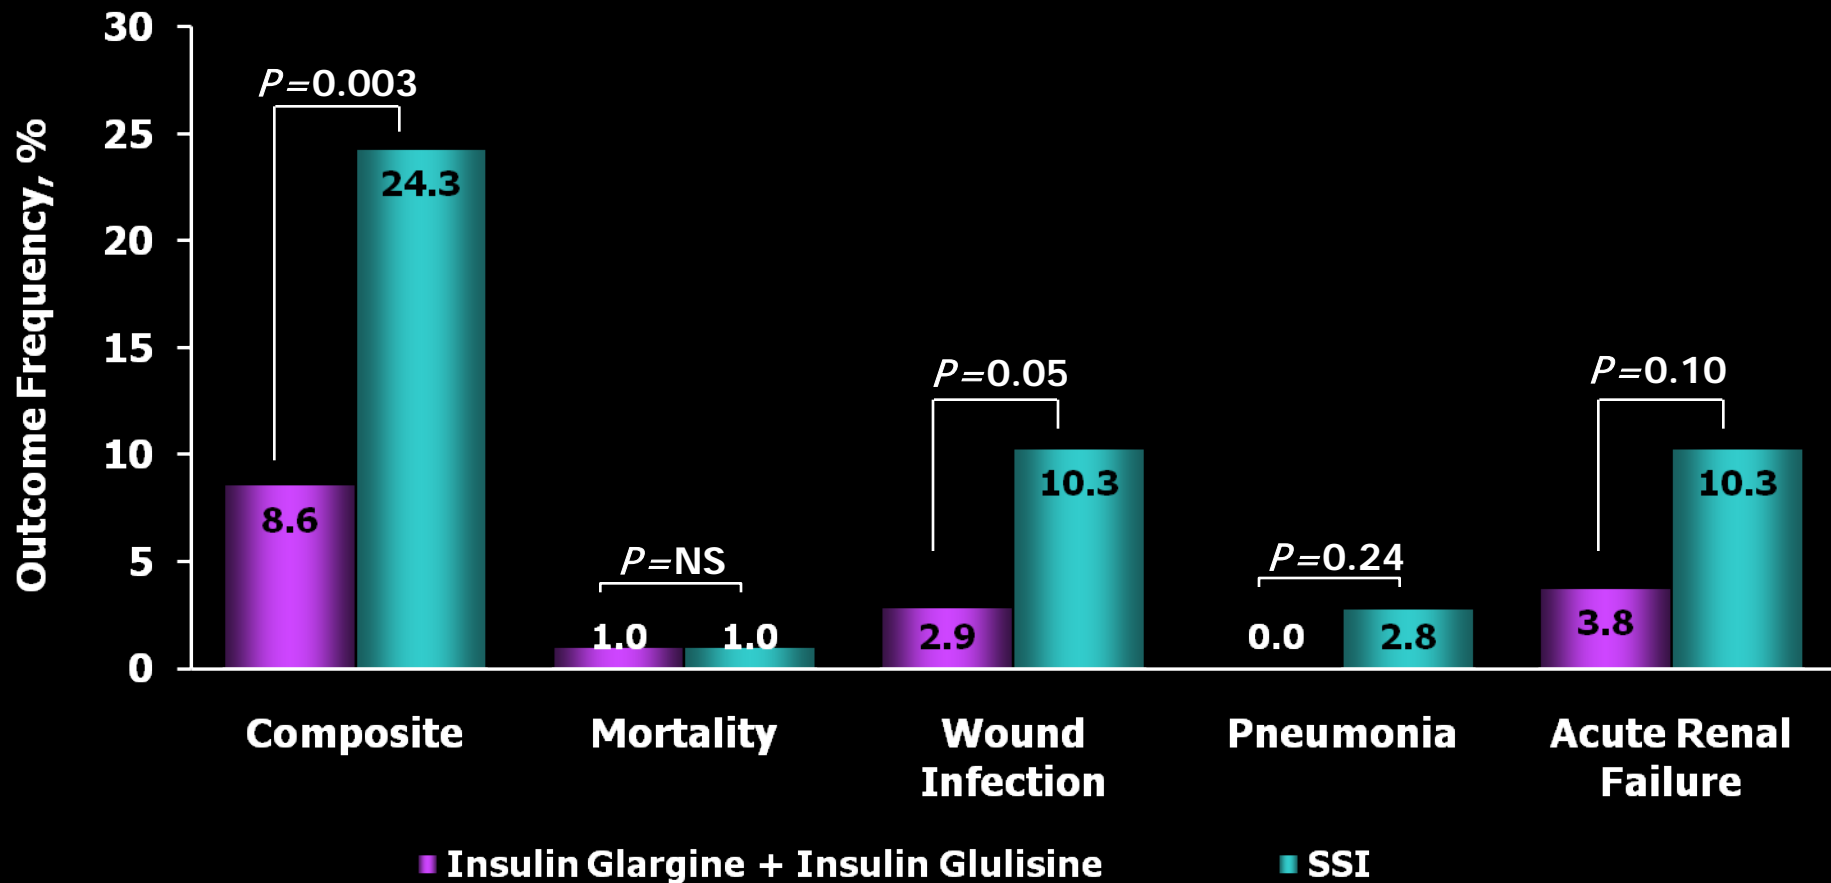

TDD: 0.5 U/kg

Half as glargine once daily  
Half as glulisine before meals

SSI

4 times/day for BG >140 mg/dl

# RABBIT Surgery Trial: Postoperative Complications

# Hospital 'Basal-Bolus-Correction' Insulin Therapy

## Basal

Typical dose:  
~20-50 U/day

- suppresses hepatic glucose production
- BID dosing, based on weight, insulin sensitivity, prior dosing requirements
- ▶ start @ 0.2-0.3 units/kg/day (or convert from currently effective insulin dose.)

## Bolus

Typical dose:  
~2-10 U/meal

- "meal insulin" blunts postprandial BG spikes
- BID AC dosing, based on (carb count)
- weight, insulin sensitivity & prior dosing requirements
- ▶ start @ 0.05 units/kg/meal

**Use same type of insulin !  
(e.g., Lispro)**

## Correction '1700 Rule'

Typical scales  
(start @ 150 mg/dl):  
1 - 2 - 3 - 4U  
2 - 4 - 6 - 8U  
3 - 6 - 9 - 12U

**If on 68 U/day:  $1700 / 68 = 25$   
1 U will drop BG by 25mg/dl**

# Admission Orders

## Patients on Oral Agents

1. Generally, hold oral agents. (Usually a hospitalized patient will have developed at least a temporary contraindication.)
2. For *well controlled* patients:
  - Eating: RISS AC; + Basal soon if needed
  - NPO: RISS Q6 hrs; + Basal soon if needed
3. For *poorly controlled* patients:
  - Eating: Basal-Bolus-Correction
  - NPO: Basal-Correction

# Admission Orders

## Patients on Insulin

1. De  
co  
✓ Adjust insulin doses every 1-2 days to achieve BG target.
  2. Fo  
•  
•  
✓ Predict insulin needs if there is a nutritional change or if steroids started/stopped.  
•  
•
  3. Fo  
•  
•  
✓ Consult Endocrinology or Diabetes Service if control is elusive.  
•  
•  
✓ Anticipate the ultimate discharge regimen.
- (T1DM: ? IV insulin if very ill, pre-op, etc.)

# **Avoidable Pitfalls in Inpatient Diabetes Management**

- **Not checking an HbA1c**
- **Prolonged use of RISS**
- **Holding basal insulin in T1DM**
- **Not rapidly adjusting insulin for situations that are likely to lead to glucose excursions (NPO, steroids)**
- **Trying to control severe hyperglycemia with SQ insulin (switch to IV insulin infusion if BG >300-350 & SQ insulin unsuccessful after 4-6 hrs.)**
- **Not anticipating the discharge plan**
- **Discharging a patient on an overly complex regimen**

An aerial photograph of a city, likely New York City, showing a dense urban landscape. In the foreground, a large, multi-story hospital complex with a prominent central tower and a helipad on its roof is visible. The surrounding area is filled with various buildings, streets, and greenery. The text "Special Situations" is overlaid in a large, bold, blue font across the center of the image.

# Special Situations

# Special Situations

## Hypoglycemia

<70 mg/dl (<40 mg/dl = 'severe')

- Can take PO → 15 g carb (4 oz. orange juice)
- NPO → 12.5 g carb IV (1/2 amp D50)
- MS changes → 15 g carb IV (1 amp D50)

**Rule of thumb: 15 g carb will ↑ BG 25-50 mg/dl**

- ✓ Document in chart
- ✓ Assess reason for hypoglycemia (food, insulin dose, sepsis, renal failure, hepatic failure)
- ✓ Re-evaluated regimen; usually decrease insulin

# Special Situations

## Tube Feeds

- **Continuous.....50% Basal  
+ 50% Reg Q6h + Correction**
  - **Cycled (8-12h)....NPH @ start**
  - **Boluses.....Regular @ start**
- 
- ⦿ **If TFs stopped, if BG <100, replace carbohydrate amount with IV dextrose (D5, D10)**
  - ⦿ **Example: If 50 cc/hr of a feed that contains 8 g/100cc, give back D5 @ 80 cc/hr (4 g/hr)**

# Special Situations

## TPN

### Treatment Options:

- 50% Basal  
+ 50% Reg Q6h (+ Correction)
- IV insulin, 100% in TPN bag (T2DM, stress hyper)
- 50% Basal + 50% in TPN bag (T1DM)

⊙ If TPN stopped, if BG <100, replace carbohydrate amount with IV dextrose (D5, D10) through peripheral line.

⊙ Example: If TPN (D20) @50 cc/hr, need D10 at @100 cc/hr.

# Special Situations

## Insulin Pumps

- Electronic devices that deliver insulin through a SQ catheter – basal rate (variable) + boluses for meals.

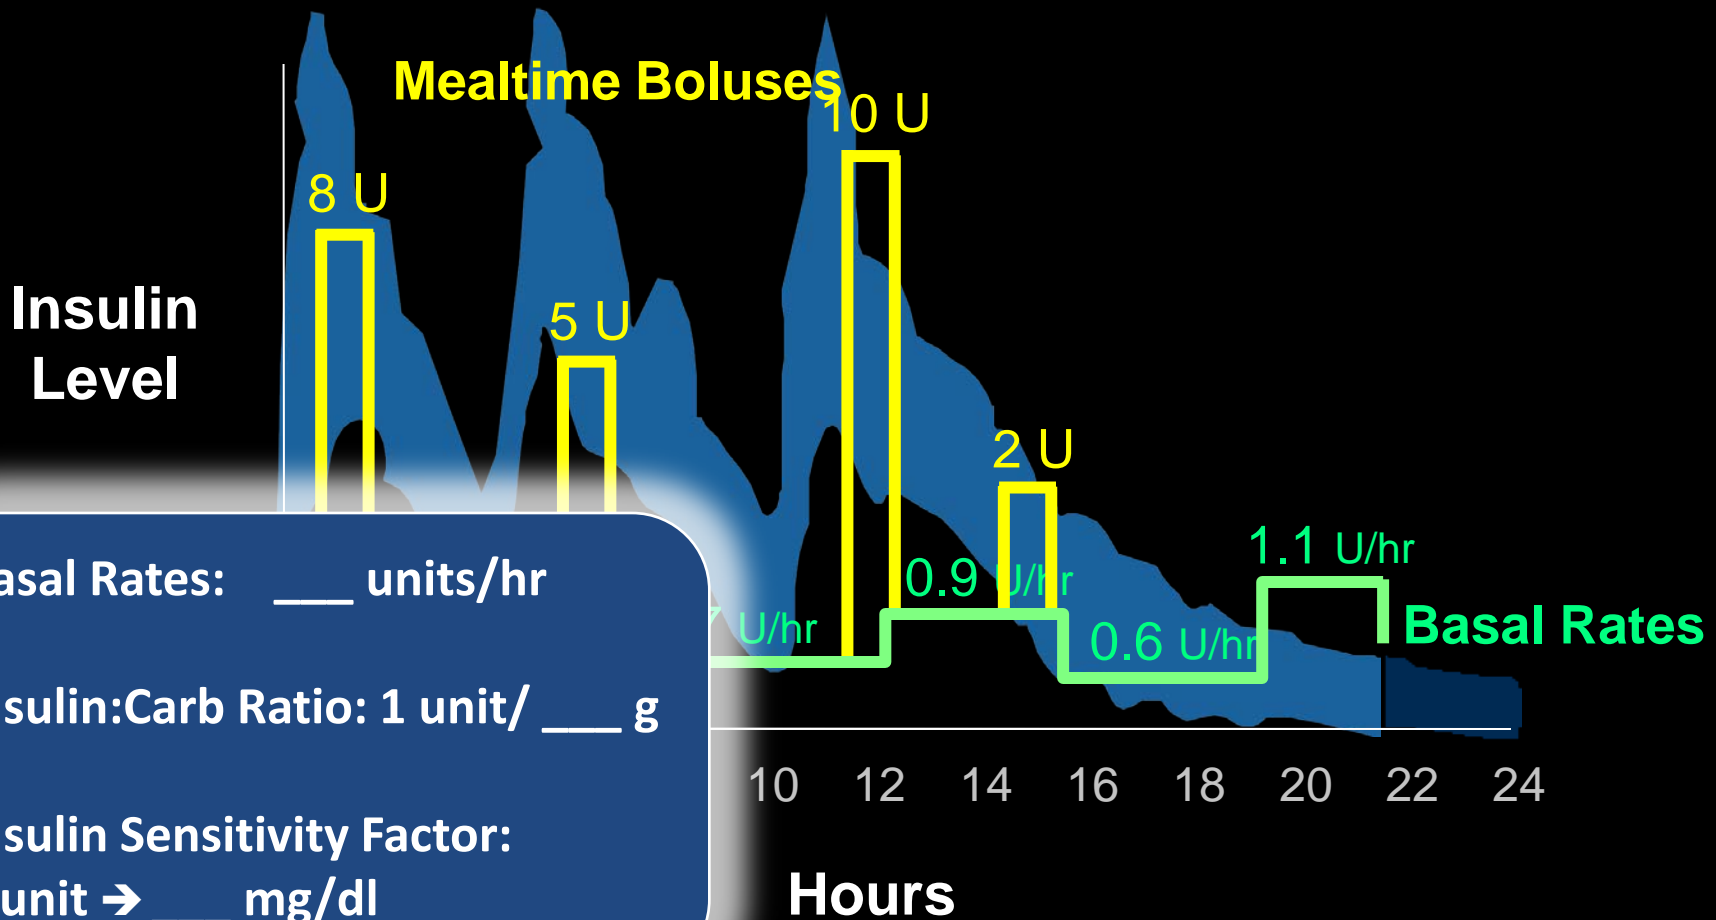

# Insulin Pumps

# Insulin Pumps

# Continuous Subcutaneous Insulin Infusion (CSII; Insulin Pump)

# Special Situations

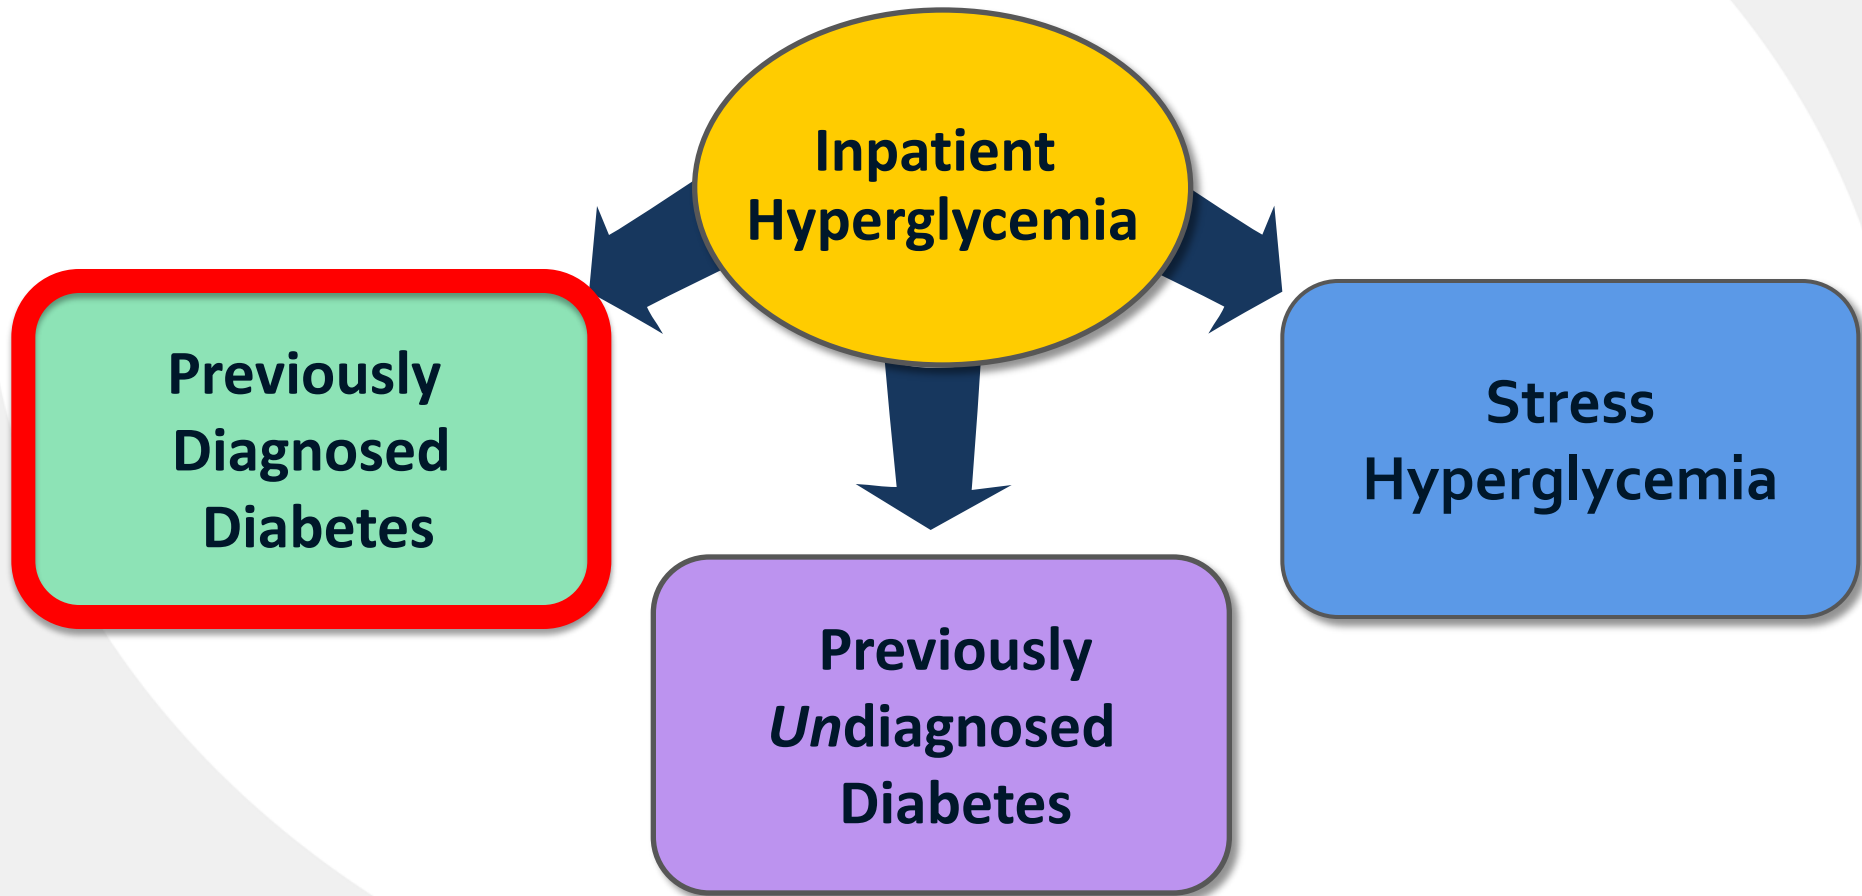

## Insulin Pumps

- Electronic devices that deliver insulin through a SQ catheter – basal rate (variable) + boluses for meals.
- Used predominately in T1DM. ‘Pumpers’ tend to be very fastidious about their BG control - reluctant to yield control to the inpatient medical team.
- Hospital personnel tend to be unfamiliar with pumps.
- Hospitals don’t stock pump supplies.
- May allow pump patients to manage own diabetes during hospitalizations, but many logistical, ethical , & medicolegal issues!

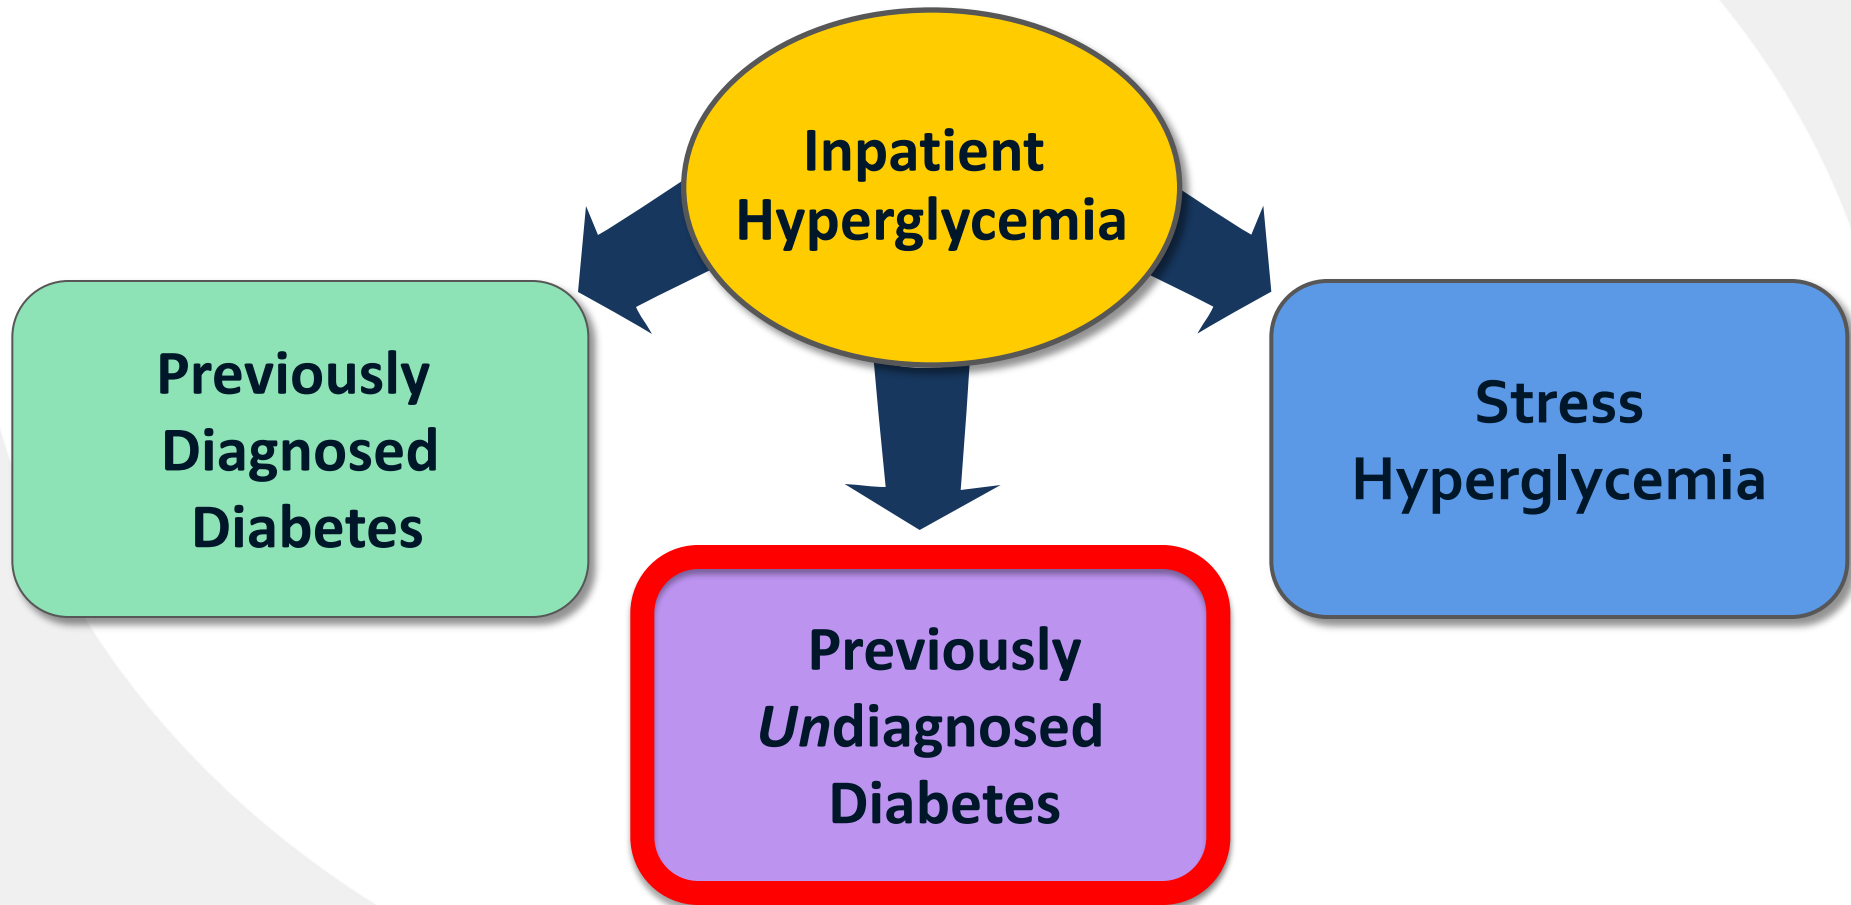

An aerial photograph of a city, likely New York City, showing a dense urban landscape. In the foreground, a large, multi-story hospital complex with a prominent central tower and several wings is visible. The hospital buildings are primarily light-colored with many windows. The surrounding city features a mix of residential and commercial buildings, including several tall skyscrapers. A river or harbor is visible in the background on the right side. The text "Discharge Planning" is overlaid in a large, bold, blue font across the center of the image.

# Discharge Planning

Frank hyperglycemia ( $\geq 200$  mg/dl [11.1 mmol/l]) also diagnostic if accompanied by classic symptoms.

# Etiologies of Inpatient Hyperglycemia

# Discharge Planning

- Be proactive – start early (1-2 days before.)
- What can this patient handle at home?
- Consider side effects, drug intolerances, comorbidities, insurance and costs.
- Rx's & supplies (med, insulins, syringes, pens, pen needles, meter, strips, lancets, etc.)
- Diabetes Education - *“Survival Skills”* training (newly diagnosed)
- Appointments: *Outpatient follow-up is key!*

# Management of Hyperglycemia in the Hospitalized Patient: Summary

1. Glucose control is important in hospitalized patients.
2. In the ICU, use IV insulin (per protocol) when BG>180; target 140-180.
3. Outside of the ICU, generally don't use oral agents. Instead: SQ insulin, preferably with physiological regimens (basal + bolus + correction)
4. Be proactive in insulin adjustments; safety first!
5. Determine optimal discharge plan (w/ outpt follow-up)
6. Use your endocrinologists or diabetes nurses/CDEs to

An aerial photograph of a city, likely New Haven, Connecticut, showing a large, multi-story hospital building in the foreground. The city is densely packed with buildings, and a body of water is visible in the background. The text is overlaid on a semi-transparent dark rectangle in the center of the image.
