

UR Medicine Virology Laboratory Seasonal Respiratory Virus Report

Week ending 23 July 2016

Report highlights: Summer seasonal respiratory virus detection remained low this week with a surprise influenza B and one RSV (no graph for RSV). Additionally, there were twelve new cases of rhino/enterovirus and five new cases of parainfluenza 3.

Results from the UR Medicine Virology lab for the previous 8 weeks are shown graphically as described below. The graphs display several components of testing, including changes in positive test results and testing volume with time, and positive test results divided into relevant age groups. The example below describes the different features of the graphs. Graphs will only be shown in the report when there is recent activity (>2 cases in the current week, or >5 cases in a given week in the reporting period). Adenovirus reporting includes only respiratory sources.
