

UR Medicine Virology Laboratory Seasonal Respiratory Virus Report

Week ending 04 February 2017

Report highlights: A total of 562 respiratory samples were submitted last week for testing. Influenza A was detected in 114 samples and Influenza B was detected in 2 samples. Overall, influenza positivity rose to 20.6%. RSV positive samples decreased to 37 with a positivity rate of 6.6%. Other respiratory viruses appearing were coronavirus and rhino/enterovirus with 16 and 9 cases respectfully.

Results from the UR Medicine Virology lab for the previous 8 weeks are shown graphically as described below. The graphs display several components of testing, including changes in positive test results and testing volume with time, and positive test results divided into relevant age groups. The example below describes the different features of the graphs. Graphs will only be shown in the report when there is recent activity (2 or more cases in the current week, or >5 cases in a given week in the reporting period, an exception being made for influenza and respiratory syncytial virus (RSV) which will be graphed when any are detected). Adenovirus reporting includes only respiratory sources.
