

UR Medicine Virology Laboratory Seasonal Respiratory Virus Report

Week ending 05 November 2016

Report highlights: Cases of rhinovirus/enterovirus declined to 16 cases this week as parainfluenza-2 increased to 4 cases. There were no cases of influenza this week but we saw 5 cases of RSV.

Results from the UR Medicine Virology lab for the previous 8 weeks are shown graphically as described below. The graphs display several components of testing, including changes in positive test results and testing volume with time, and positive test results divided into relevant age groups. The example below describes the different features of the graphs. Graphs will only be shown in the report when there is recent activity (2 or more cases in the current week, or >5 cases in a given week in the reporting period, an exception being made for influenza and respiratory syncytial virus (RSV) which will be graphed when any are detected). Adenovirus reporting includes only respiratory sources.
