

# UR Medicine Virology Laboratory Seasonal Respiratory Virus Report

Week ending 12 November 2016

*Report highlights:* Cases of rhinovirus/enterovirus increased to 26 cases this week. There was 1 case of influenza this week and 3 cases of RSV.

Results from the UR Medicine Virology lab for the previous 8 weeks are shown graphically as described below. The graphs display several components of testing, including changes in positive test results and testing volume with time, and positive test results divided into relevant age groups. The example below describes the different features of the graphs. Graphs will only be shown in the report when there is recent activity (2 or more cases in the current week, or >5 cases in a given week in the reporting period, an exception being made for influenza and respiratory syncytial virus (RSV) which will be graphed when any are detected). Adenovirus reporting includes only respiratory sources.
