

# UR Medicine Virology Laboratory Seasonal Respiratory Virus Report

Week ending 2 July 2016

*Report highlights:* Early summer seasonal respiratory virus detection was relatively low again this week with 14 cases of Rhinovirus/Enterovirus as well as 5 cases of Parainfluenza 3 and 1 case of Parainfluenza 1.

Results from the UR Medicine Virology lab for the previous 8 weeks are shown graphically as described below. The graphs display several components of testing, including changes in positive test results and testing volume with time, and positive test results divided into relevant age groups. The example below describes the different features of the graphs. Graphs will only be shown in the report when there is recent activity (>2 cases in the current week, or >5 cases in a given week in the reporting period). Adenovirus reporting includes only respiratory sources.
