Radiology / Pathology Conference

9/24/2010

Kirsten Woolf, Cytopathology Fellow
Trushar Sarang
Case 1

50 year old female with abdominal pain. Finding #1
Case 1

50 year old female with abdominal pain. Finding #1
Case 1

- **Finding #1:** Low attenuation liver lesions
ddx
  - Well defined borders
    - Cyst
    - Hemangioma (peripheral nodular enhancement)
  - Ill-defined margins: Malignancy
    - Mets – hypovascular
      - adenoca (pancreas/color)
    - Primary tumor
      - Cholangiocarcinoma
Case 1

- Finding #2:
Case 1

• Finding #3:
Case 1

• Finding #3: Differential?
Case 1

- Finding #2 & 3: Thickened/irregular colon – 4 l’s
  - Infection
  - Ischemia (watershed, mesenteric gas)
  - Inflammatory bowel disease
  - Infiltrative tumor
  - Penetrating injury – fish bone, hematoma, etc.
Case 1

• Which of these are you worried about?
Case 1

- What would you do with **Finding 1**?
Case 1

• What would you do with Finding 1?
Case 1

• What would you do with Finding 1?
Case 1

- Finding 2?
Case 1

• Finding 2?
Case 1

- Finding 3?
Case 1

- Finding 3?
Case 1

• Finding 3?
Case 1

- Finding 3?
Case 1

- One of the peritoneal nodules was biopsied

- Case 1 PATH
Peritoneum, biopsy (at time of cholecystectomy):

Involved by adenocarcinoma, consistent with colonic origin. Immunohistochemical stains for CK20 and CDX2 are positive. CK7 and CA125 are negative. Mucicarmine histochemical stain is positive. This staining pattern suggests colonic origin.
Colon, sigmoid, biopsy:

Well differentiated adenocarcinoma.
Colon Carcinoma

- Vast majority are adenocarcinoma
- #2 cause of cancer death in US
- Risk factors: older age, obesity, IBD, polyposis syndrome, diet, family history
- Clinical presentation: rectal bleeding, anemia, change in bowel habits, abdominal pain
- Metastasis: most common to regional lymph nodes and liver, less likely peritoneum, ovary, lung
Case 1

- 50 year old female with abdominal pain
Case 1

Long GB LLD
Case 1

- Outside hospital HIDA suggested biliary dyskinesia
- During cholecystectomy surgeon finds peritoneal nodules and biopsies them
Case 1

- Metastatic disease, stage D
Case 1

- After chemotherapy
Case 1

• Key points:
  – Be wary of subtle but real findings
  – Would it make a difference in this patient?

<table>
<thead>
<tr>
<th>Staging, Grading, or Classification Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>Surgical pathologic (modified Dukes) staging of colon cancer with TNM correlation</td>
</tr>
<tr>
<td>• Stage A (T1N0M0): Limited to mucosa ± submucosa</td>
</tr>
<tr>
<td>• Stage B (T2 or 3 &amp; N0M0): Limited to serosa or into adjacent tissues</td>
</tr>
<tr>
<td>• Stage C (T2 or 3 &amp; N1M0): Lymph node metastases</td>
</tr>
<tr>
<td>• Stage D (any T and N, M1): Distant metastases</td>
</tr>
</tbody>
</table>

• Early detection could improve prognosis

<table>
<thead>
<tr>
<th>Prognosis</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Overall 5 year survival is 50%</td>

<tr>
<td>• Duke’s stage B: 64-78%</td>
</tr>
<tr>
<td>• Duke’s stage C: 27-33%</td>
</tr>
<tr>
<td>• Duke’s stage D: 5-14%</td>
</tr>
</tbody>
</table>
Case 2

- 69 year old male with fever of unknown origin
Case 2

- 69 year old male with fever of unknown origin
Case 2

• Right cecal mass differential
  – Malignancy:
    • Metastasis (melanoma, lymphoma)
    • Colon cancer (10% in the cecum)
      – Strands of soft tissue extend into the pericolonic fat
      – PET-CT uptake is 2x higher than nonmalignant lesions
  – Benign: Leiomyoma, Lipoma, Fibroma, Myxoma
Case 2

- History of colon cancer, status post right colectomy
Case 2

- History of colon cancer, status post right colectomy

Differential?
Case 2

- Does this change your differential?
Case 2

- How about now?
Case 2

- Right paratracheal mass differential
  - Primary tumor of esophagus or trachea
  - Metastasis to esophagus or less likely lymph node
  - Less likely infection/inflammatory lymph node
Case 2

• Does this add information?
Case 2

- Does this add information?
Case 2
• Case 2 Path
Neck mass, ultrasound-guided
FNA: Papanicolaou stain
Neck mass, ultrasound-guided FNA: Papanicolaou stain
Neck mass, ultrasound-guided FNA: MSA Immunostain
Neck mass, ultrasound-guided
FNA: S100 Immunostain
Neck mass, ultrasound-guided fine needle aspiration:

Rhabdomyoma, adult type.

Comment: The tumor consists of polygonal to elongate cells with abundant cytoplasm and round generally centrally located nuclei. Scattered cells display cross striations which are best seen on Diff-Quik stained slides.

Immunohistochemical stains:

- Muscle specific actin (MSA) – positive
- S100 – negative
Soft tissue, cervical paraesophageal, biopsy: H & E stain
Soft tissue, cervical paraesophageal, biopsy: H & E stain
Soft tissue, cervical paraesophageal, biopsy:

Fibrofatty tissue with scant benign thyroid epithelium and colloid.
Minute piece of slightly abnormal skeletal muscle.
Rhabdomyoma, adult type

- Rare benign tumor of skeletal muscle
- Extracardiac tumors not associated with tuberous sclerosis
- Seen in older adults, 75% male
- Head and neck/oral cavity most common location
- Recurrent potential if incompletely excised
Case 2

- **Rhabdomyoma**
  - Benign tumor of skeletal muscle (hamartoma)
  - Most common primary cardiac tumor of children
  - Associated with TS in 86%
Case 2

• Rhabdomyoma
  – Also commonly affects the floor of the mouth/tongue in adults
  – Rhabdomyosarcoma is most common head and neck malignancy in children
Case 2

• Management?
  – ?Benign esophageal lesion
  – Anterior abdominal wall – malignant?
Case 3

- 66 year old female, here to evaluate thoracic aneurysm
Case 3

- 66 year old female, here to evaluate thoracic aneurysm
Case 3

- Solitary pulmonary nodule
  - Granuloma
  - Malignancy/solitary metastasis
  - Infectious
  - Hamartoma

- Other: collagen vascular dz, sarcoid, Wegener’s
Case 3

- How would you work this up?

Lung, LUL, CT-guided
FNA: Diff-Quik stain
Lung, LUL, CT-guided
FNA: Papanicolaou stain
Lung, LUL, CT-guided FNA:
Cell Block, Hematoxylin & eosin stain
Lung, LUL, CT-guided FNA: Cell Block, Immunohistochemical stains

TTF-1

Napsin A
Lung, Left upper lobe, CT-guided fine needle aspiration:

Malignant tumor cells present derived from adenocarcinoma.

Immunohistochemical stains:

Positive: TTF-1, Napsin A
Negative: p63

The findings support adenocarcinoma of the lung.
Lung, LUL, biopsy:
Hematoxylin and eosin stain
Lung, LUL, biopsy:
Hematoxylin and eosin stain
Lung, LUL, biopsy: Immunohistochemical stains

Napsin A

TTF-1
Lung, left upper lobe, biopsy:

Adenocarcinoma consistent with pulmonary primary.

Immunohistochemical stains:
Positive: TTF-1, Napsin A
Negative: p63

The results support the diagnosis and a pulmonary origin.
Pulmonary adenocarcinoma

- Lung cancer is #1 cause of cancer death
- Adenocarcinoma: most common lung carcinoma in females and non-smokers
  - 65% peripheral location
- Positive immunostaining for CK7, TTF-1, Napsin A, and negative for CK20
- Positive intracellular histochemical staining for mucin

- Broad classification is non-small cell carcinoma (80%) versus small cell carcinoma (20%)
- Overall 5 year survival in general: 10-15%
- 50% of non-small cell carcinomas are metastatic at diagnosis vs. 80% of small cell carcinomas
  - Hilar, mediastinal, supraclavicular lymph nodes most common
  - Also adrenal, liver, brain, bone, opposite lung, pericardium, kidney
Case 3

- Lung cancer
  - Small cell
  - Non-small cell
    - Adenocarcinoma
      - BAC subtype
    - Squamous cell
    - Large cell
Case 3

• Key points
  – PET-CT is not optimal for places where there is
    • Motion (breath hold and cardiac gating)
    • Small size (<2 cm)
    • Hypometabolic tumor (BAC, carcinoid 1/3)
  – Suspicious FDG-PET findings should be biopsied without following for growth on CT
  – Suspicious CT morphology should be biopsied with negative PET
PET-CT vs size

09/29/2005
Slice 84: Z = 65,790

09/29/2005
Slice 104: Local Z = 65,790

• Case 4 Path
Retroperitoneum, mass, CT-guided FNA: Diff-Quik stain
Retroperitoneum, mass, CT-guided FNA; Papanicolaou stain
Retroperitoneum, mass, CT-guided
FNA: Cell block, H & E stain
Retroperitoneum, mass, CT-guided fine needle aspiration:

Malignant tumor cells present derived from poorly differentiated carcinoma, most likely squamous cell carcinoma.

Cell block and cytologic preparations examined.
Soft tissue, retroperitoneal, biopsy, Hematoxylin & eosin stain
Soft tissue, retroperitoneal, biopsy, Hematoxylin & eosin stain
Soft tissue, retroperitoneal, biopsy:

Squamous cell carcinoma involving soft tissue/skeletal muscle, consistent with metastatic carcinoma.
Cervical carcinoma

- Still #1 cause of cancer death among women in many countries, now #8 in US
- 95% of cervical squamous cell carcinoma associated with high risk HPV
- 2/3 stage I or II when diagnosed (in US)
- Spreads via lymphatics to regional nodes or direct extension to vagina, uterus, parametrium, etc.
- Distant mets to aortic/mediastinal LN, lung, bone, ovary, peritoneum
- 5 year survival stage I: 95%, II: 80-90%, III: 50%, IV: 25-35%
Case 4

- Lymphatic or hematogenous spread to retroperitoneum:
  - Testicular ca, melanoma, ovary, prostate, lung, breast
Case 5

46 year old female with progressive left hearing loss
Case 5

46 year old female with progressive left hearing loss
Case 5

- What is your differential?
Case 5

- Cerebellopontine angle mass differential
  - Meningioma
  - Schwannoma
  - Metastases
  - Epidermoid
  - Arachnoid cyst

Axial T1WI MR shows a low signal mass in the right CPA cistern that insinuates and enlarges the foramen of Luschka (white arrow) and scallops the ventral cerebellar hemisphere (white open).

Axial T2WI FS MR shows a high signal lesion (white arrow) in low CPA cistern. Note the anterior displacement of proximal CN8 by arachnoid cyst (white open). The high signal results from absence of CSF flow.
Case 5

Axial 5mm Average Registered rCBV (ml/100g)

Vitrea®
Batch #13
W/L: 5/3
#392-401
Case 5

- What is the differential?
Case 5

Jugular foramen mass differential

– Glomus vagale tumor
– Carotid body tumor (if large)
– Meningioma
– Schwannoma
– Metastases
Case 5
Case 5

• What do you think of the carotids?
Case 5
Case 5

- Case 5 Path

Jugular foramen, CT-guided
FNA: Papanicolaou stain
Jugular foramen, CT-guided FNA: Cell block, H & E stain
Jugular foramen, CT-guided FNA: Cell block, Immunostains

Synaptophysin

CD56

Chromogranin

S-100
Jugular foramen, CT-guided fine needle aspiration:

Paraganglioma.

Cell block and cytologic preparations examined.
Paraganglioma

- Glomus jugulare tumor when arises in jugular foramen of temporal bone
- Most common tumor of middle ear
- 85% arise in jugular bulb causing middle ear mass or mass in external auditory canal
- Often present with conductive hearing loss or tinnitus
- Histologically usually appear benign, but can’t predict which ones will metastasize
- Can be locally invasive and often present late, but only about 5% metastasize
Case 5

- Salt and Pepper on T1W (sometimes T2)
Case 5

- Glomus tumors are paragangliomas – named for location
  - Glomus jugulotypanicum – middle ear and jugular foramen
  - Glomus vagale tumor – from the vagal nerve
  - Carotid body tumor – will splay the carotids
  - Glomus tympanicum – in the middle ear

- Not to be confused with glomus body tumors of fingers
  - chemoreceptors
